

Background Noise Transmission Quality for Wideband Systems

H. W. Gierlich, S. Völl, F. Kettler
(HEAD acoustics GmbH)

P. Jax
(IND, RWTH Aachen)

– Workshop on Wideband Speech Quality in
Terminals and Networks

supported by:

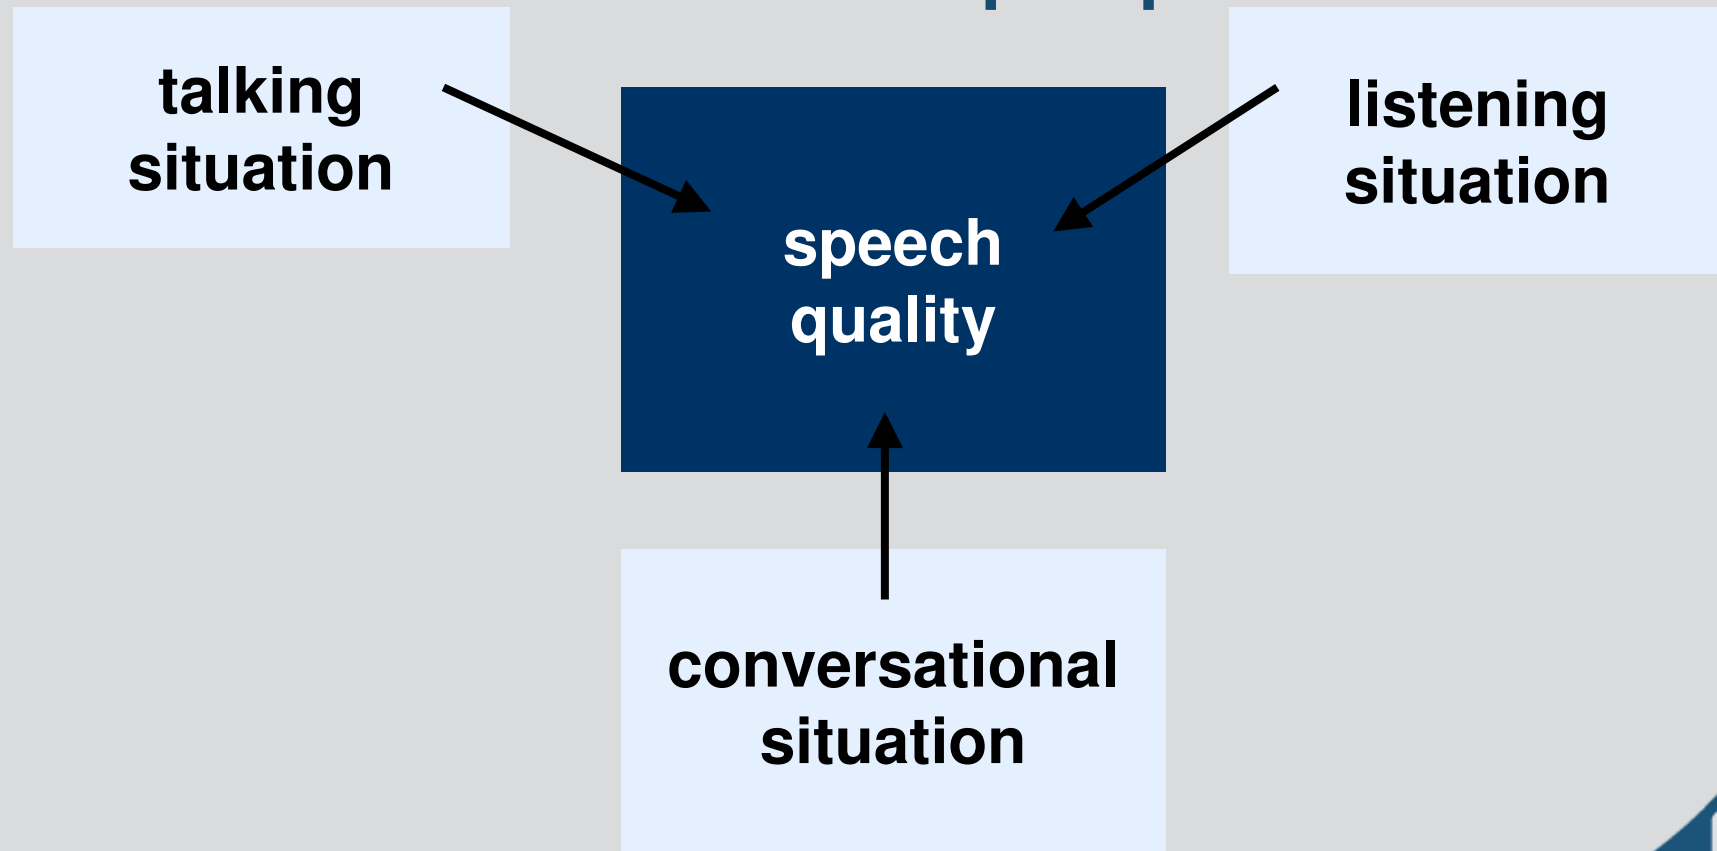

Outline

- General aspects of speech quality in wideband systems
- Subjective tests on background noise transmission
- Objective evaluations
 - Test procedures
 - Test signals
- Summary

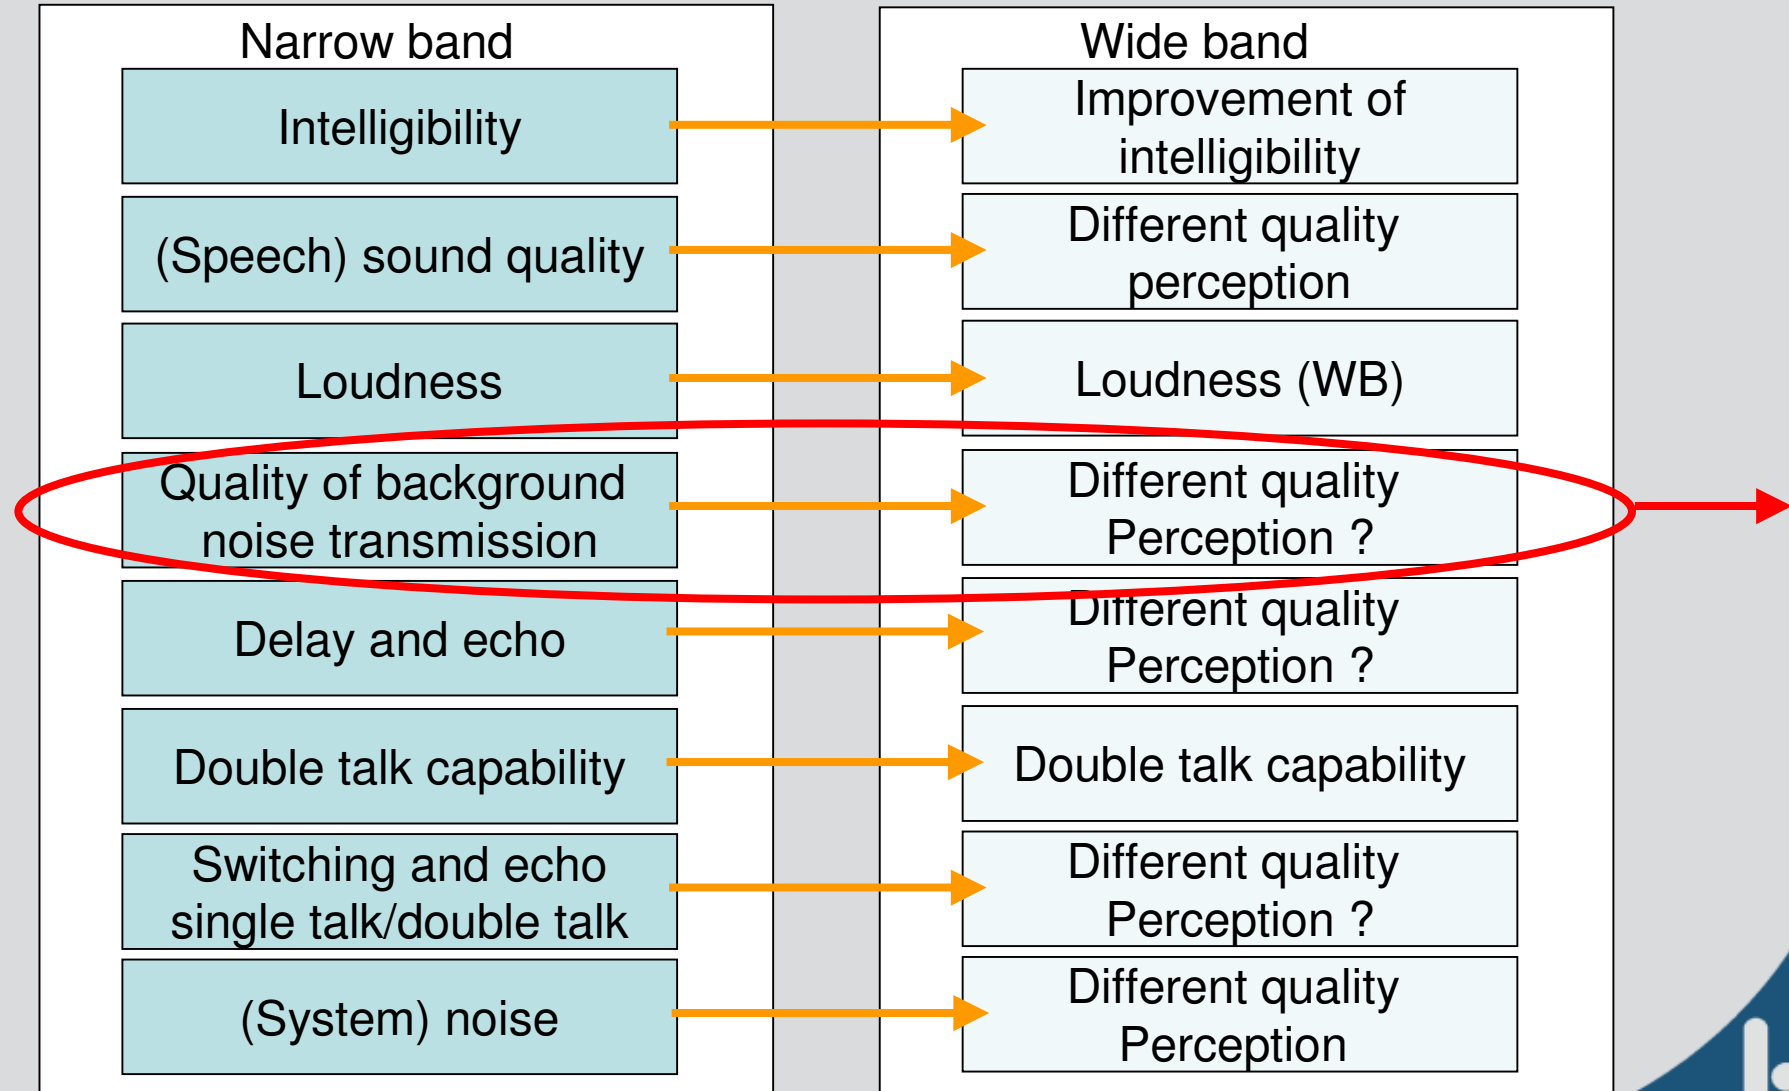

Speech Quality Parameters

... from the user's perspective

Auditory Parameters

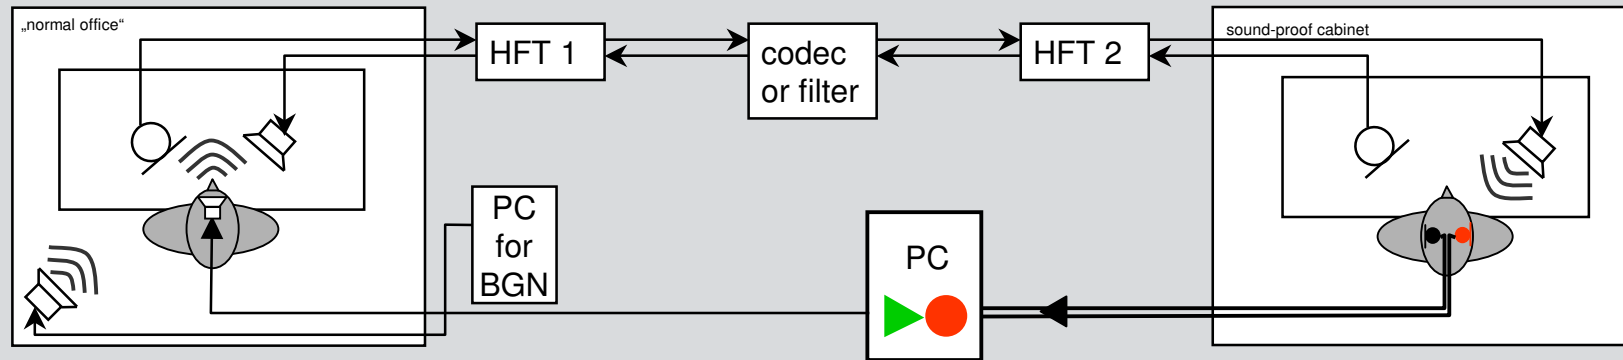

Outline

- General aspects of speech quality in wideband systems
- **Subjective tests on background noise transmission**
- Objective evaluations
 - Test procedures
 - Test signals
- Summary

Background noise tests

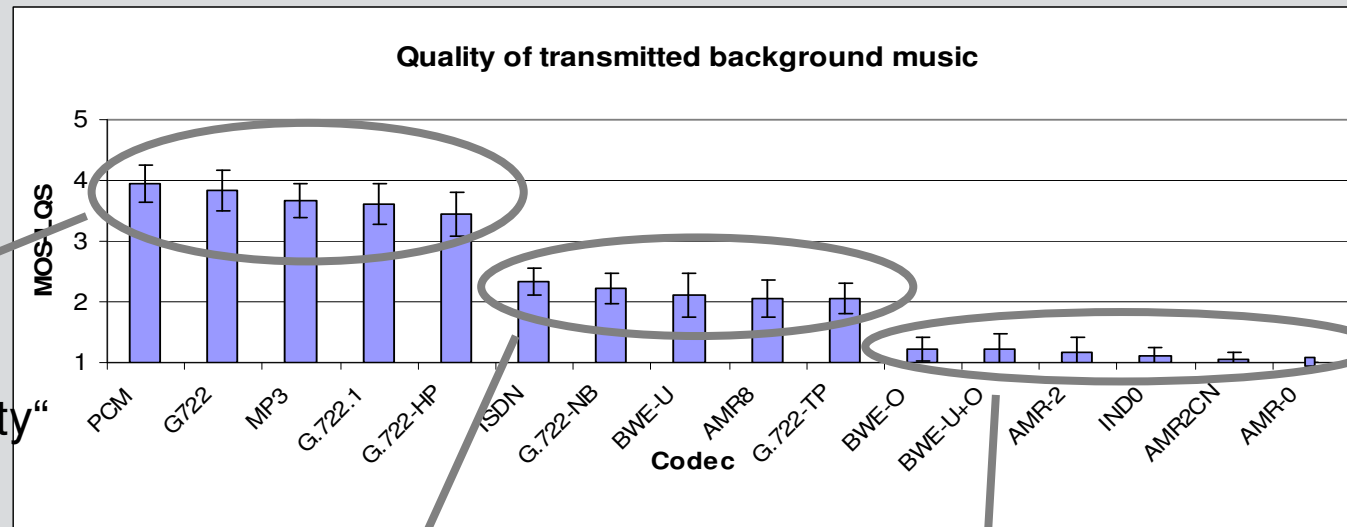

- Recording listening samples:

- Listening:
test persons listen to artificial head recordings
- ACR scale:
excellent – good – fair – poor – bad

Results

- 3 quality levels with significantly different MOS - values

- wideband
- good „intelligibility“ of music

- narrowband
- good „intelligibility“ of music

- mostly wideband
- bad „intelligibility“ of music

Outline

- General aspects of speech quality in wideband systems
- Subjective tests on background noise transmission
- **Objective evaluations**
 - Test procedures
 - Test signals
- Summary

Comparison FFT – Hearing model

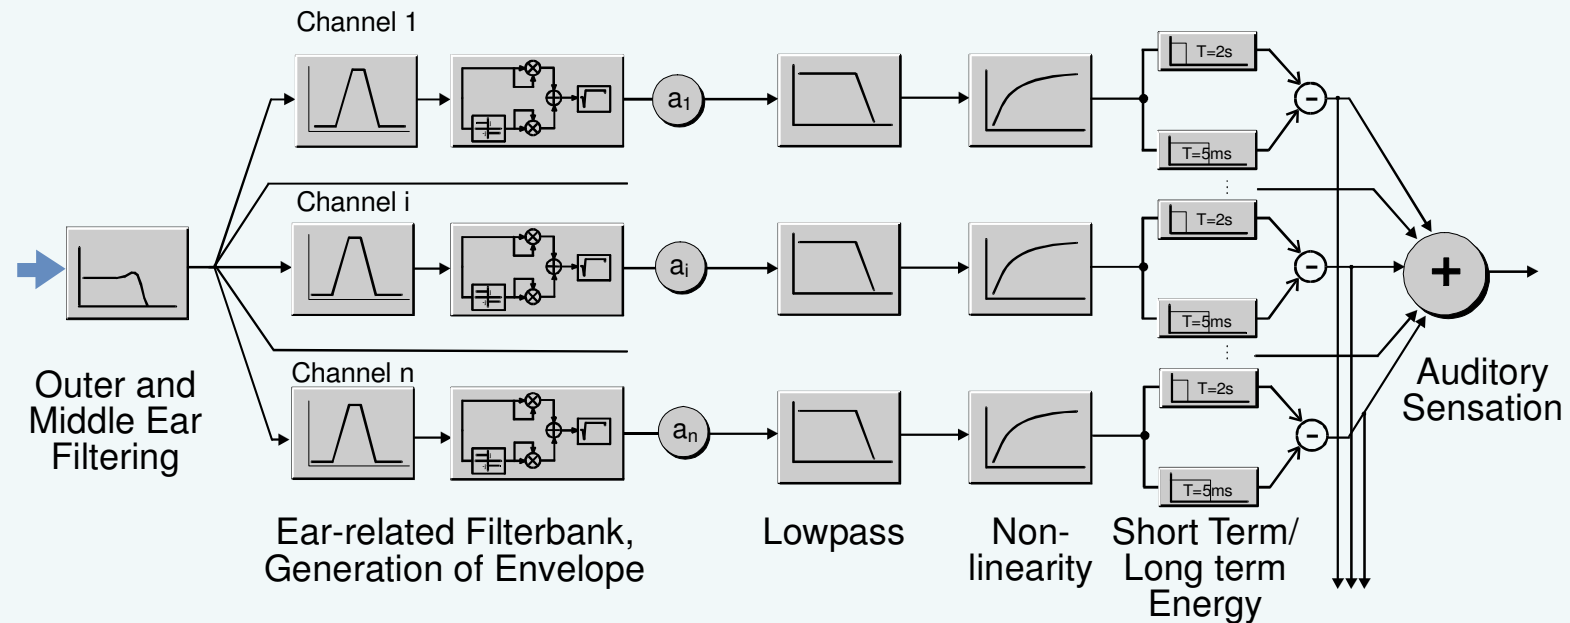

G.722.1

IND 12,4 kbit/s

→ Hearing model in general gives a better representation of the impairments perceived

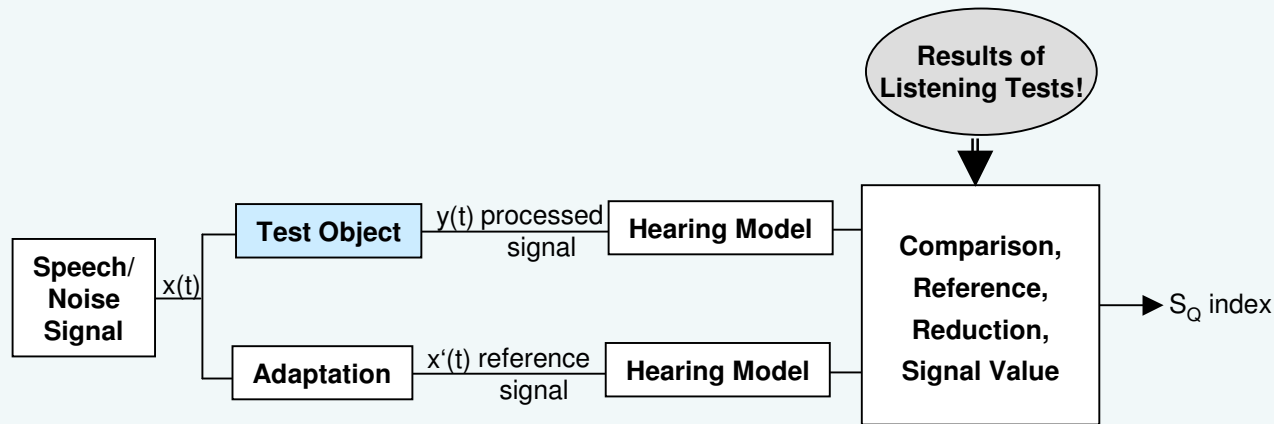

Hearing Model & Relative Approach

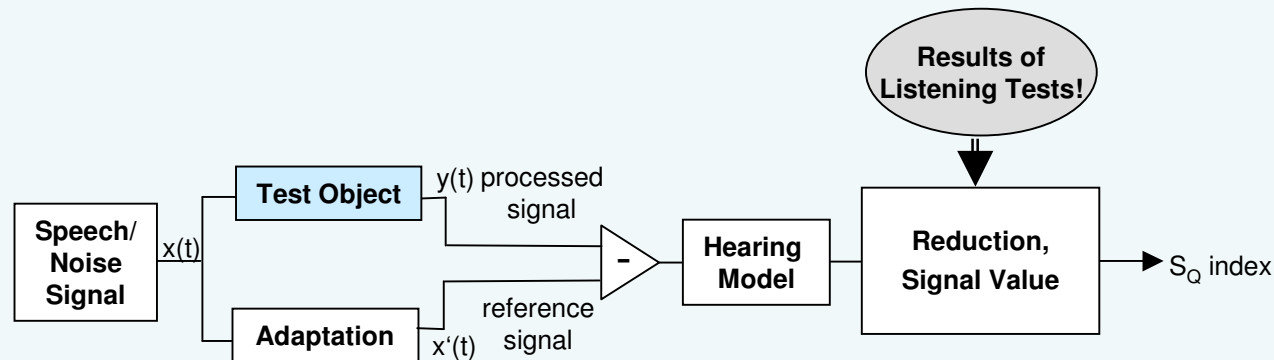

Model of the "Relative Approach":
Hearing model and calculation of the energy differences in critical bands

Hearing Model Based Approaches

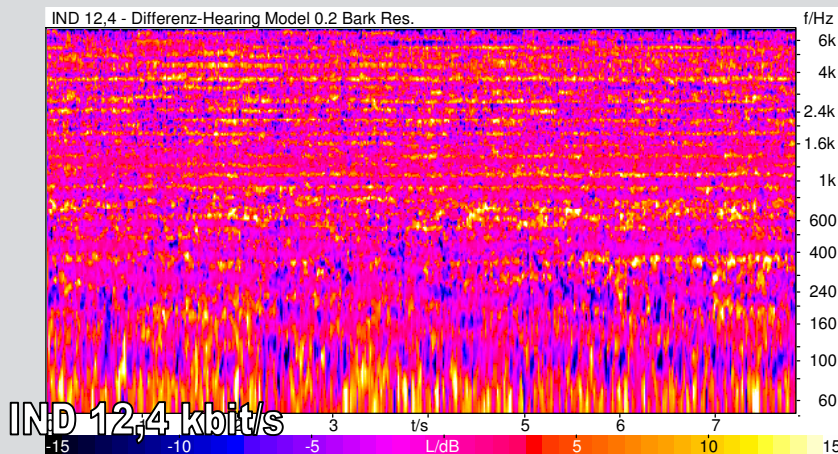

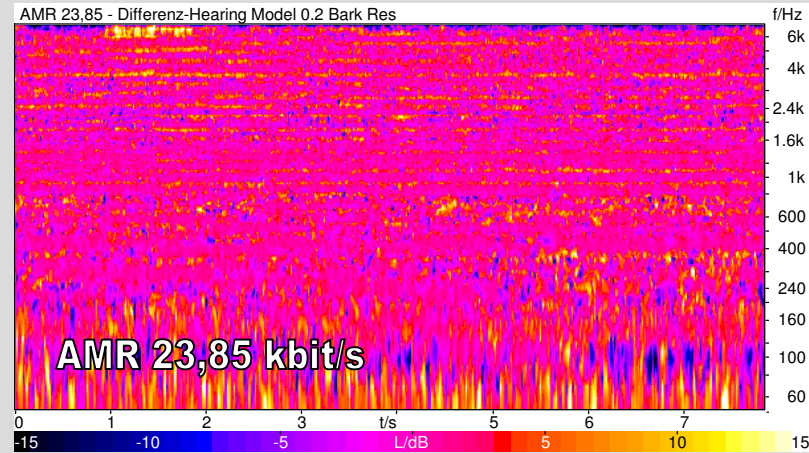

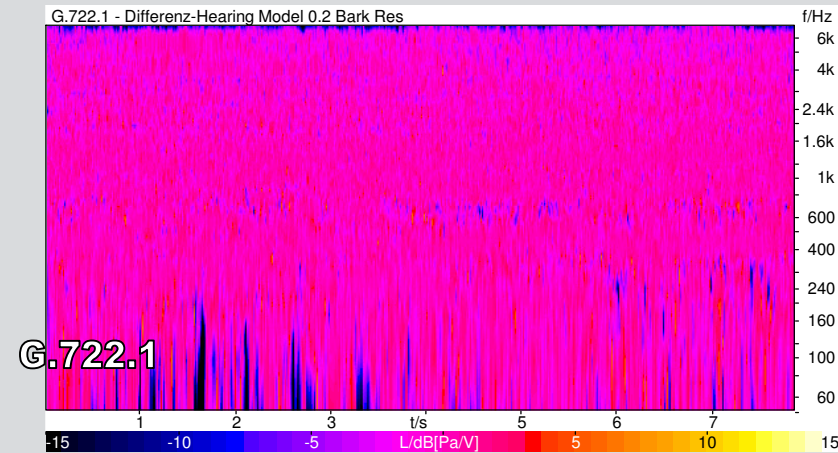

Hearing model approach based on a reference hearing model output

Hearing model approach based on a differential signal

Objective Analysis

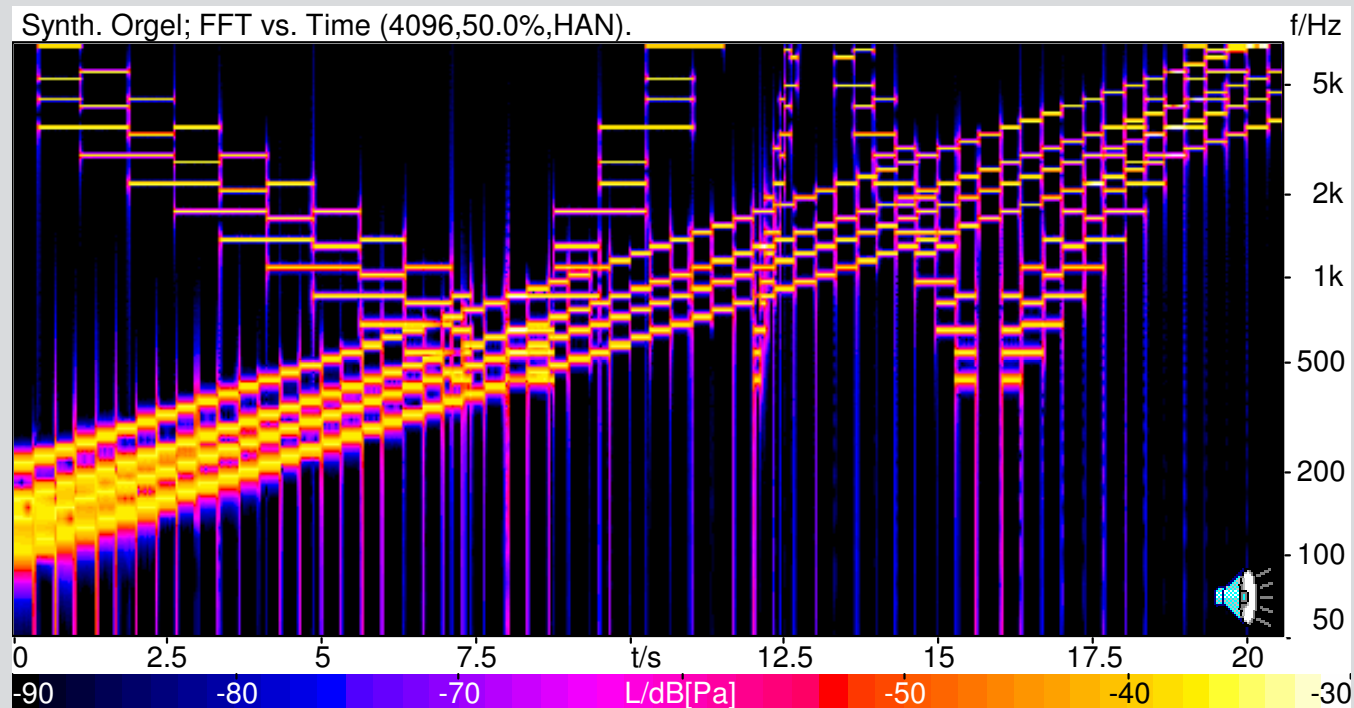

Hearing model output –
referenced to hearing model output of input signal

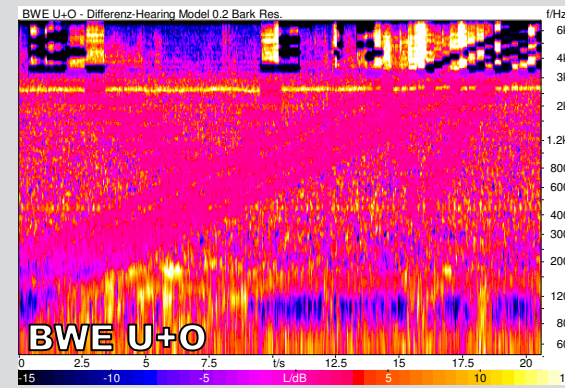

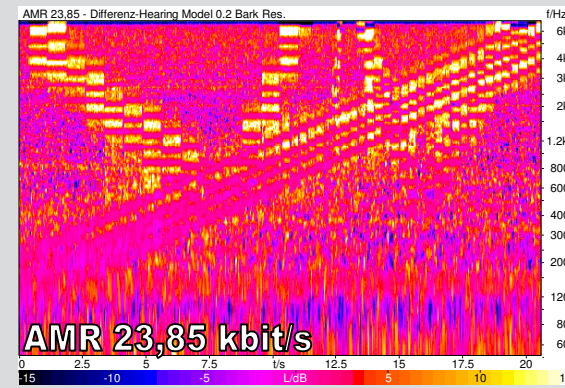

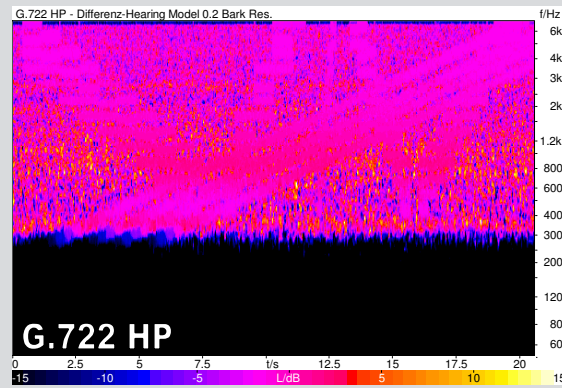

Background Noise Testsignal

Mathematically defined signal based on major chords

- representing time and frequency structure of tonal background noises

Results

Classification

of the different disturbances (based on the hearing model output)

50-300 Hz	Spectral distortion		Distortion in time	Expected MOS-score
	300-3400 Hz	3400-7000 Hz		
< 3 dB	< 3 dB	< 3 dB	----	> 3,5
< 3 dB	< 12 dB	> 12dB	----	2 – 3
< 3 dB	> 12dB	< 12 dB	----	1 – 2
< 3 dB	> 12dB	> 12dB	----	1 – 2
< 12 dB	< 3 dB	> 12dB	X	1 – 2
	< 3 dB	< 3 dB	----	3 – 3,5
	< 3 dB	> 12dB	X	1 – 2
< 3 dB	< 3 dB		----	2 – 3
< 12 dB	< 3 dB		----	2 – 3
	< 3 dB		----	2 – 3

Conclusions

- **Proposed test signal in combination with the hearing model based reference analysis approach is very promising for the evaluation of (tonal) background noise**
- **To do:**
 - **Additional subjective testing**
 - **Use additional background noises**
 - **Further development of the test procedure**
